Semi-structured interviews were conducted with $n=18$ participants with a lived experience of bipolar and $n=5$ healthcare professionals. The interviews comprised open ended questions and a Likert-item questionnaire. The responses to the interview questions were analysed using content analysis and corpus linguistic methods to develop a classification system of risk-taking behaviours. The Likert-item questionnaire was analysed statistically and insights from the questionnaire were incorporated into the classification system. This metadata document should be read in conjunction with the *Annotation_Guidelines* to understand how to interpret the interview transcripts.

The transcripts have been anonymised in accordance with the ethics approval granted by Lancaster University in December 2021 (FHMREC21042). The transcripts are provided here in two formats - .docx for the transcripts without any metadata, and .xml for the fully annotated transcripts (see *Annotation_Guidelines* for a description of the annotation tags. Table 1 shows the participant identifiers used in this study.
